Why bother about NLP?

Fast growing electronic clinical data

Rapid adoption of Electronic Health Records (EHR).

Increasing requirements for electronic documentation of healthcare.

Exponentially growing quantities of electronic investigation results information (imaging, genetic testing, etc.)

So what's the problem?

Mostly unstructured information, like **narrative text**, dictated and transcribed or typed in.

Most structured information coded with administrative and reimbursement-oriented terminologies.

Why bother about NLP?

What does the EHR contain?

- Documents
 - History and Physicals
 - Clinical notes, Consult notes
 - Operative reports
 - Surgical pathology reports
 - Progress notes, Letters
 - Orders
 - Discharge summaries
- Imaging / Radiology
- Prescriptions (pharmacy; CPOE)
- Laboratory results
- Administrative information

Why bother about NLP?

Why bother about NLP?

CDS information needs

Structured (i.e., using some data model) and **coded** (i.e., labeled with some standard terminology) clinical information

...but most EHR content is narrative text, unstructured, and is therefore inaccessible for CDS.

Detailed clinical information, at various levels of granularity

...but most terminologies used were created for mortality and morbidity public health statistics, and for reimbursement (i.e., ICD-9-CM, CPT-4), and don't allow for detailed, clinical care-oriented coding.

Why bother about NLP?

Possible solution to these problems

Natural Language Processing (NLP) can be used to automatically extract various types of clinical information from the EHR narrative text content

⇒ Clinical Information Extraction (IE)

Natural Language Processing (NLP) can be used to automatically extract various types of clinical information from the EHR narrative text content

⇒ Clinical Information Extraction (IE)

Why bother about NLP?

Clinical information extraction

Information Extraction (IE) involves extracting **predefined** types of information from text (e.g., people, diseases, symptoms, medication doses).

The development of IE applications in the biomedical domain has been far more advanced than in the clinical domain, mostly for two reasons:

- Extremely limited availability of clinical text because of patient confidentiality and privacy reasons.
- Characteristics of clinical text and related difficulties to analyze it.

Clinical Information Extraction

The Automated Problem List

What was the problem?

An electronic problem list was already available at IHC, but

- it was often incomplete, inaccurate, not timely...not used!
- the problem list was becoming a central component of the EHR and was to be used by many applications (CPOE, documentation, knowledge access, etc.).

HOSPITAL COURSE
 On arrival in my office, he was cyanotic and had a saturation of 70% . He was transported by ambulance to the hospital where he was admitted in respiratory distress . His INR was 1.7 at that time . During his hospital stay, he was thought to be in congestive heart failure due to his 3+ edema in his extremities and his enlarged heart with evidence of pulmonary edema on chest x-ray He was diuresed for several days down to 2 to 3 liters . He was given albuterol . His baseline creatinine was 1.5 and the goal was to diurese him until that increased . Despite loss of significant weight, he was still hypoxic . He was on adequate anticoagulation but concern was raised that he might still have a pulmonary embolus, so he was sent to PE lab, and was found to have chronic DVTs in both legs . He was assumed to be having pulmonary embolus because of this and ultimately I got a spiral CT scan which demonstrated this pulmonary embolus His . Coumadin was reversed with vitamin K and his heparin was continued with a goal of stopping it and placing an IVC filter . On 10/03/2000, he had increased oxygen requirements so it was thought it was not going to be possible to discharge him to home. .

DISPOSITION
 Social work discussed his illness with his son and daughter and arrangements were made to transfer him to St. John's Hospital for rehabilitation. .

DISCHARGE MEDICATIONS
 One baby aspirin a day, and oxygen at 8 liters by nasal cannula . He was to follow up with me one week after his discharge from the nursing home. .

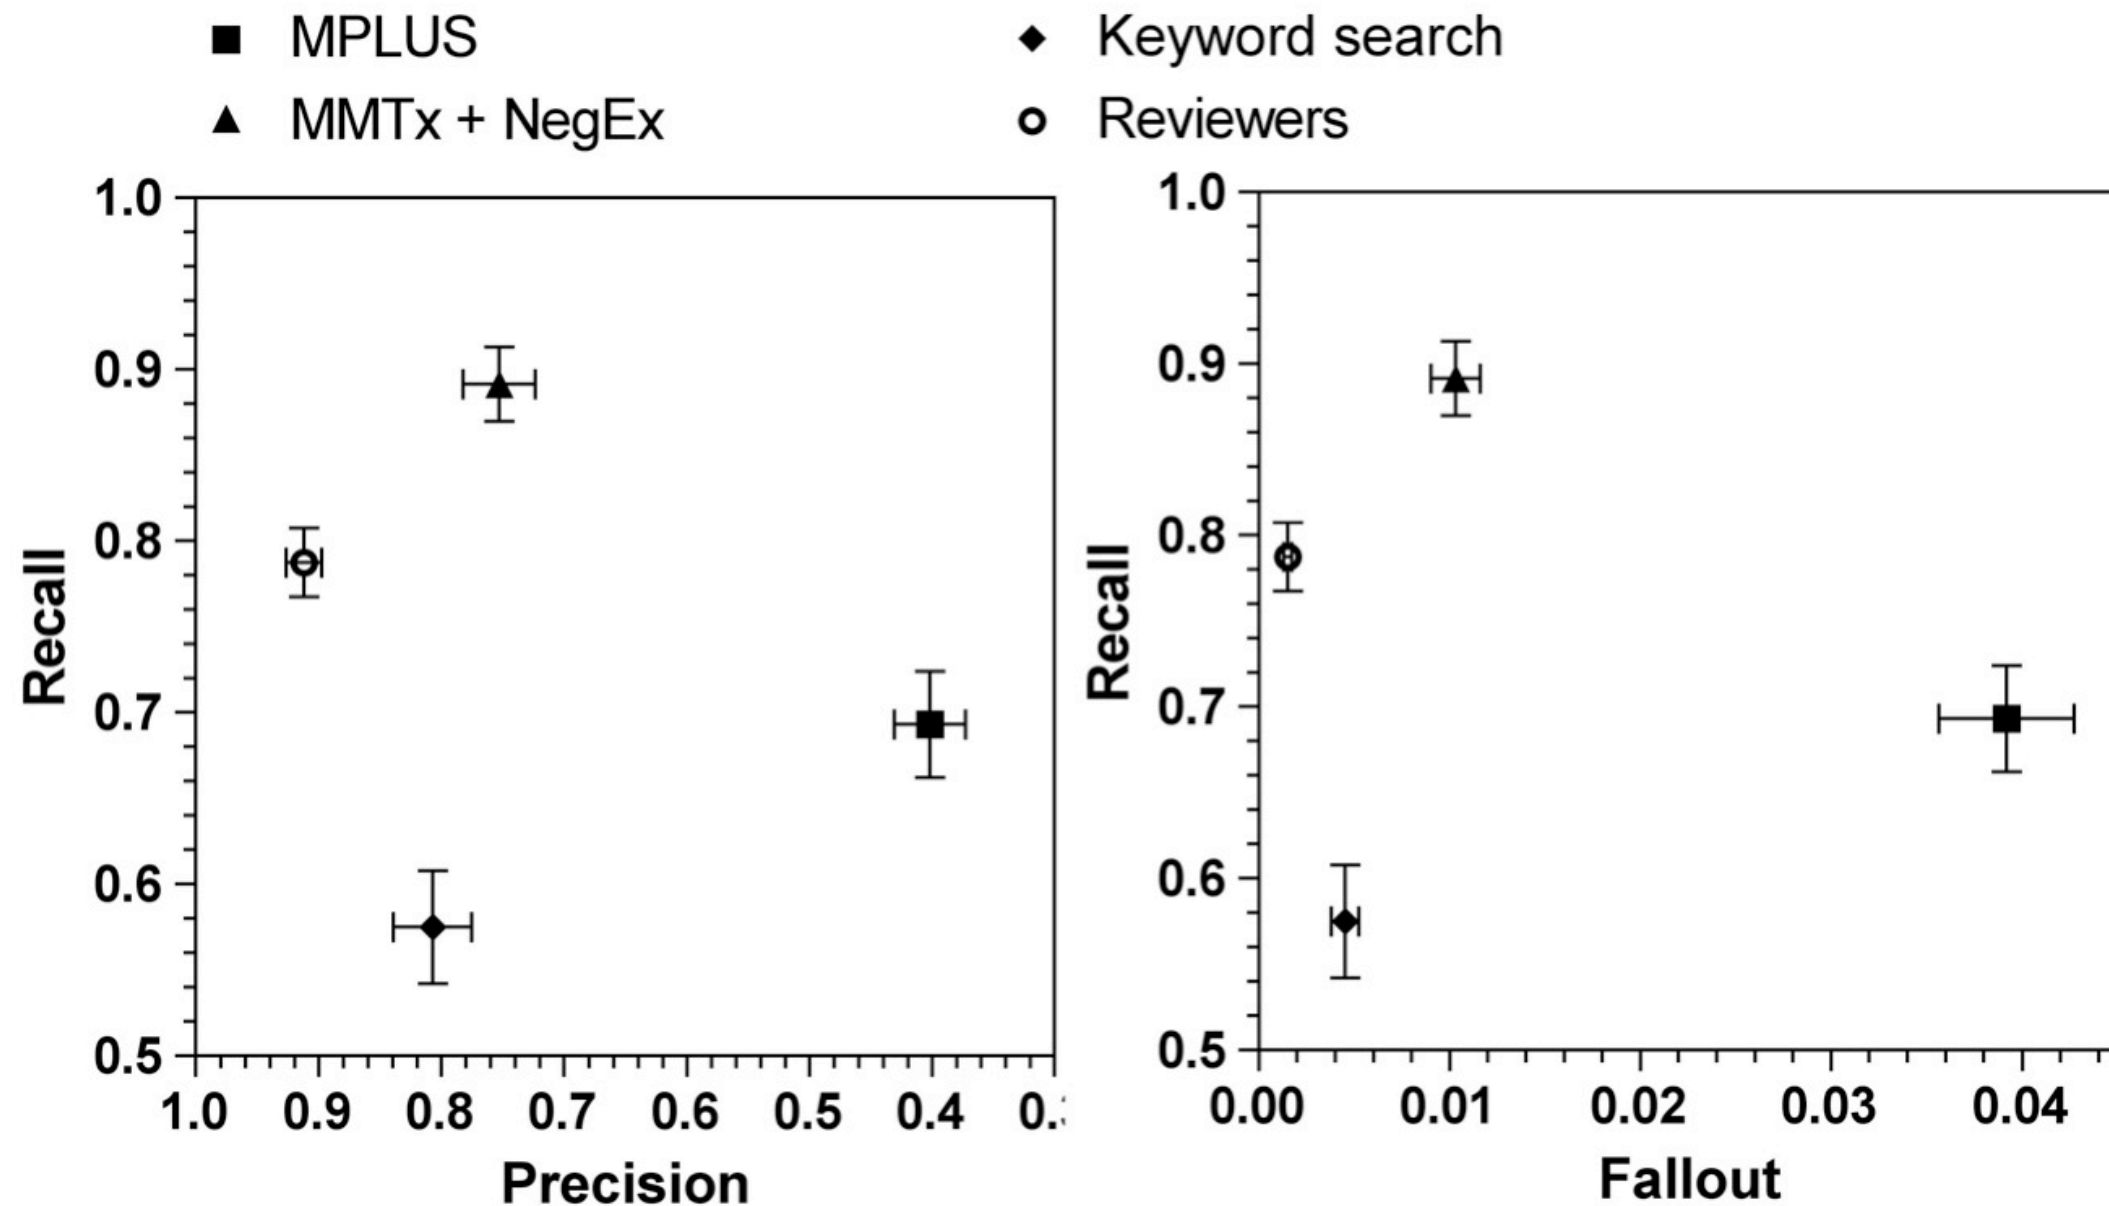

DISCHARGE DIAGNOSES
 1. Pulmonary embolus 2. Chronic deep vein thrombosis 3. Inferior vena cava filter placement . 4. Chronic hypoxia . 5. Sleep apnea. .

Clinical Information Extraction

Textractor (for medications extraction)

Why extract medications?

- CPOE and e-Prescribing systems becoming widely available in the healthcare system.
- Large proportion of medications actually taken by the patient only mentioned in narrative clinical text documents in the EHR:
 - Prescribed in another institution or private practice,
 - Bought over-the-counter,
 - Prescribed before the introduction of CPOE.

Clinical Information Extraction

Texttractor (for medications extraction)

Why extract medications?

- Large proportion of medications actually taken by the patient only mentioned in narrative clinical text documents in the EHR:
 - Prescribed in another institution or private practice,
 - Bought over-the-counter,
 - Prescribed before the introduction of CPOE.

⇒ This is where automated medication information extraction could (and will) help!

Textractor (Medications Extraction)

2009 i2b2 Medication Extraction Challenge Task :

Identification of medications and related details in discharge summaries:

- Medication name (brand name, generic name, drug class)
- Dosage
- Route
- Frequency of the administration (incl. “as needed”)
- Duration of the treatment
- Reason(s) for the prescription

Corpus

1249 discharge summaries, de-identified and re-identified with realistic surrogates, split in a training corpus (696 documents) and a testing corpus (553 documents).

Textractor

Application details

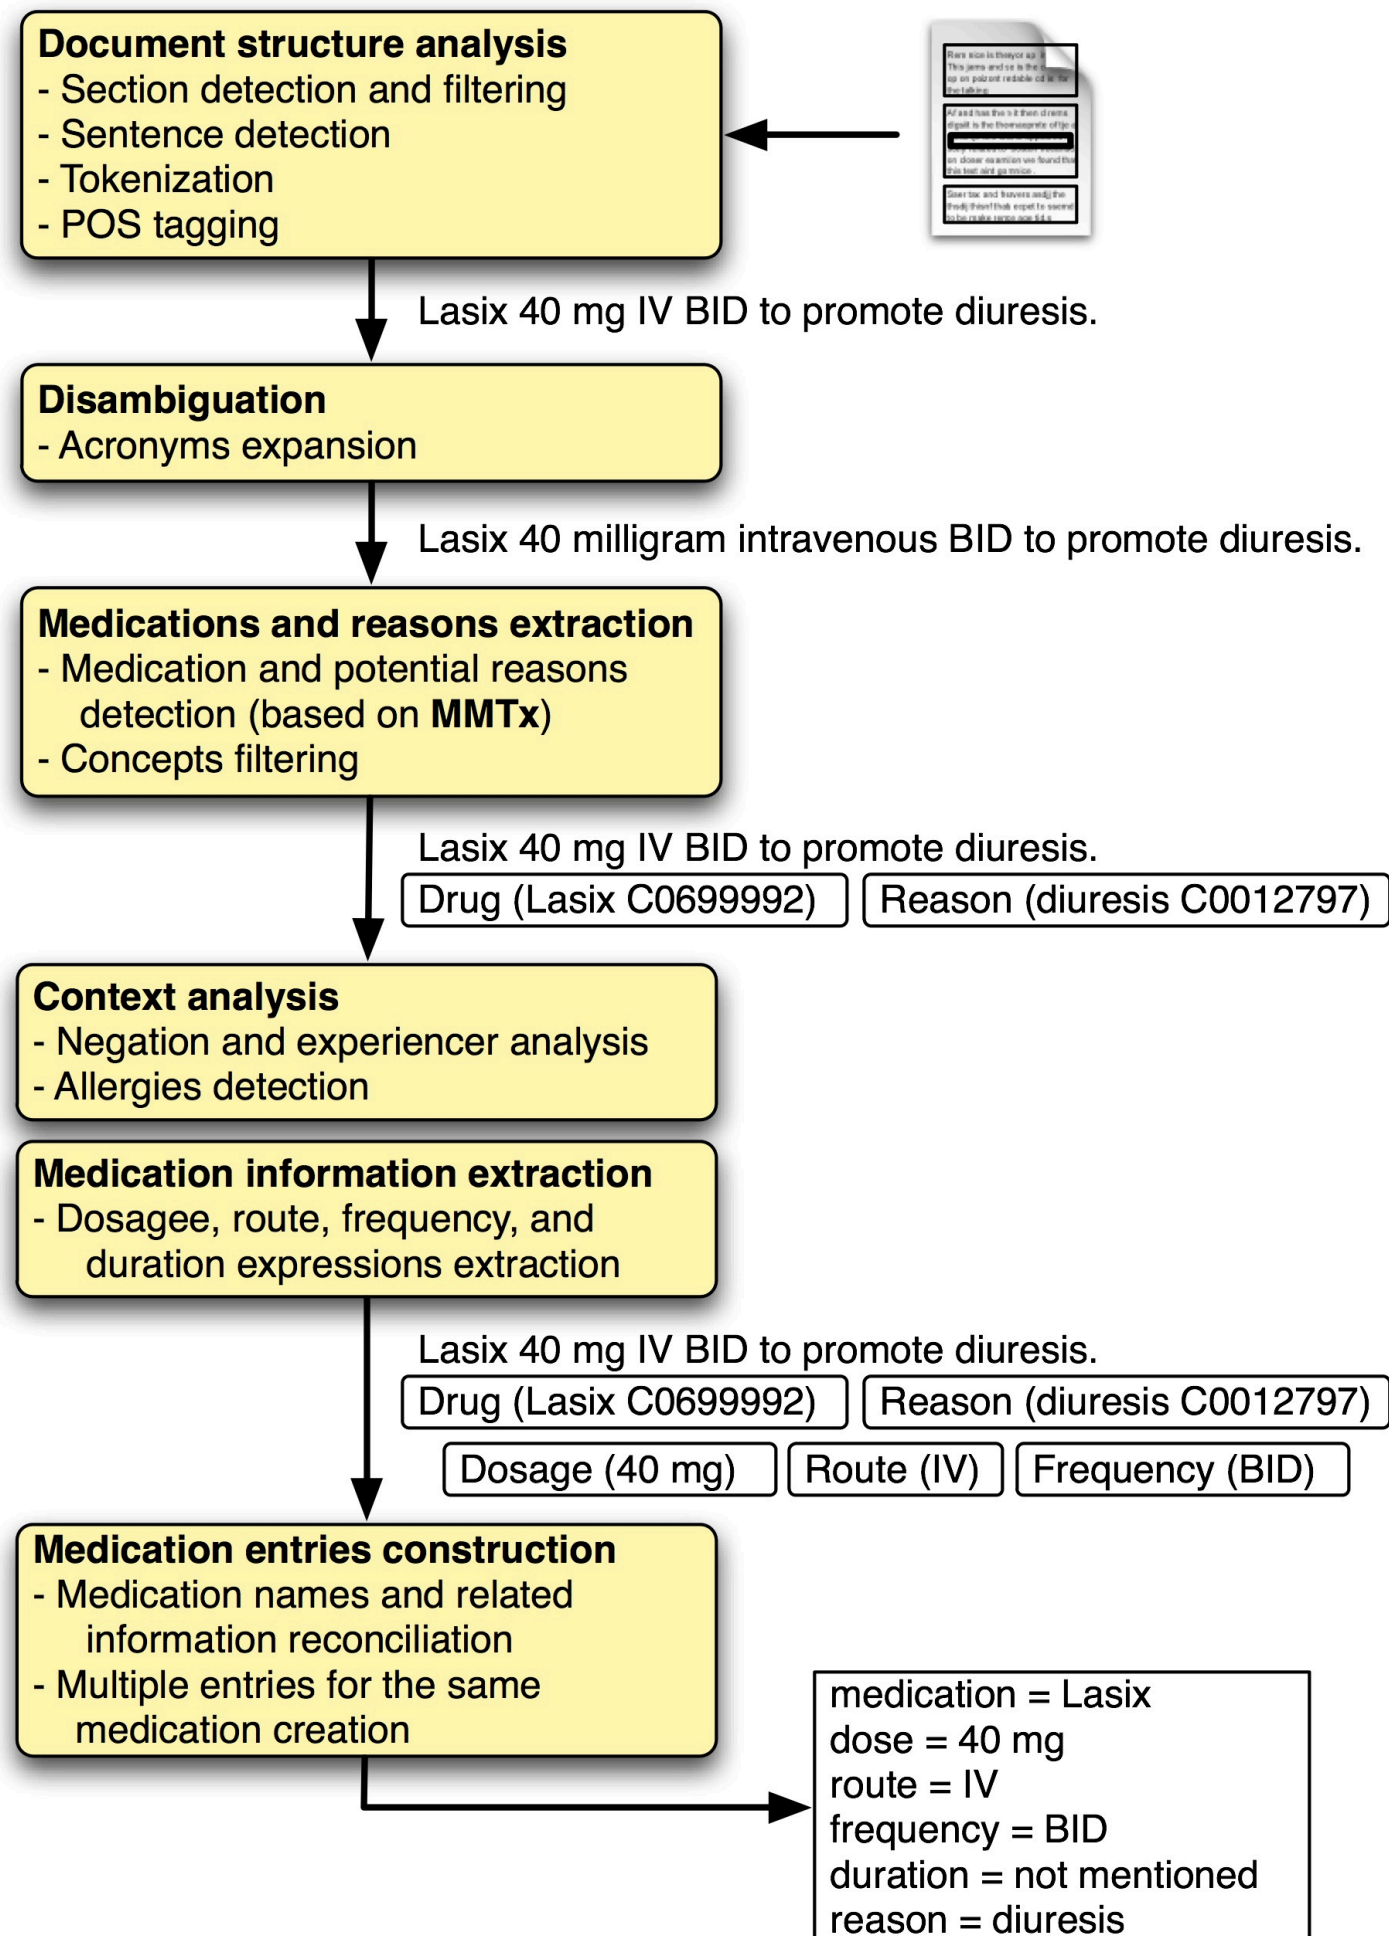

Built on UIMA, with functionalities developed as modules (TAEs), organized in a pipeline.

Several components based on OpenNLP tools, wrapped and retrained.

Uses MMTx (version 2.4.C), wrapped for UIMA in its first version. Dictionary lookup now based on Lucene.

Context analyzer based on the ConText algorithm, with improvements for this task.

Regular expressions used to extract dosage, route, etc.

Conclusions

For customers of automatically extracted clinical information, or CDS based on this information, trust can be based on several factors:

- Ensuring that there is a **human expert in the loop** for all clinical information generated by NLP and becoming part of the EHR.
- Allowing users to know the **origin of the extracted information** (and the methods used; and therefore use NLP methods that make it possible).

With trust in the NLP-generated information, even moderate performance is acceptable (moderate sensitivity, but sufficient PPV).
